## CELULITIS EOSINOFILICA

Se trata de una dermatosis inflamatoria recurrente de patogénesis desconocida. Las lesiones cutáneas inicialmente semejan celulitis bacteriana e histopatológicamente presentan eosinofilia dérmica, histiocitos y figuras en llama. Ha sido descrito principalmente en adultos y sólo 17 casos en niños, con un rango de edad entre 3 sem. a 14 años, la mayoría varones, pueden haber lesiones ampollares, tiene curso benigno, con eosinofilia periférica, siendo el único tratamiento efectivo los esteroides sistémicos a altas dosis.
